

Getting Started With PGP

Digital Signature and Encryption for
E-mail and Files

Problem: E-mail is insecure

- **More like a postcard than a letter**
- **Can be read by any number of people in transit**
- **If recipient's account is compromised, may be read by unauthorized person(s)**
- **Network sniffing may capture and reveal content to unauthorized person(s)**

Getting Started with PGP

Problem: E-mail is easily forged

- Current protocols date back to early 1970s
- Headers, especially “From:” are ridiculously easy to forge
- If sender account is compromised, may not actually have been sent by that person
- **How can you verify the sender’s identity?**
- A small demonstration (`spoofmail.php`)

Getting Started with PGP

Solution: PGP (“Pretty Good Privacy”)

- Developed in 1991 by Phil Zimmerman
- Based on public/private key pair cryptography principle developed by Whitfield Diffie and Martin Hellman
- Provides highly secure encryption and signature for any digital data - including e-mail

Getting Started with PGP

PGP: Drawbacks

- Not all that “user friendly”
- Public/private key concepts take some getting used to
- Doesn't scale well to large user groups
- If your private key is lost, corrupted or compromised, you have to generate a new one and start all over again – all your data is gone!

Getting Started with PGP

PGP: How Does It Work?

- Let's start with some basics of cryptography, and the high-level mathematics underneath it
- Don't worry, this is just to give you an idea of what's going on.

Getting Started with PGP

Some Quick Definitions

- **Cryptography**: encrypting and decrypting messages
- **Algorithm**: a mathematical function used for encryption, decryption and verification
- **Key**: a string used for encryption and decryption

(Digital) Keys

- **In computer cryptography, a key is simply a bunch of bytes of varying length, depending on the type of cryptography being used**
 - “Symmetric” cryptography generally relies on keys of 128 bits or more (e.g. most web browser SSL sessions)
 - “Asymmetric” cryptography requires keys of minimum 1024-bit length (2048 is typical these days)
- **A properly generated key can only be cracked by “brute force” - and only then after thousands of years (even at today’s processing speeds)**

Getting Started with PGP

Keys: Encrypting/Decrypting (A bit oversimplified)

One typical way keys are used to encrypt/decrypt is by use of “exclusive-OR” (XOR) logic:

- If the bit to be encrypted is the same as the corresponding key bit, the encrypted bit is 0
- If they are different, the resulting encrypted bit is 1
- Without the key, you can't be sure what the original bit was
- Simple keys like this are vulnerable to “known text” attacks

TEXT	KEY	RESULT
0	0	0
0	1	1
1	0	1
1	1	0

“Symmetric” Cryptography

- Relies on both sender and recipient having identical copies of the encryption key - or access to a “third party” that can verify that both have the correct key (e.g. online “certificate authority”)
- Can use relatively low key lengths
 - 128 bits is more or less standard
 - 56 bits has been cracked
- **Problem: secure key distribution**

Getting Started with PGP

“Asymmetric” Cryptography (aka “Public/Private Key”)

- **Sender generates a “public/private” key pair**
- **The “public” key can be freely given out**
 - Published on website, in e-mail sigs, etc.
 - Some people put them on the back of their business cards
- **The “private” key is guarded at all costs**
 - If lost, corrupted or compromised, a new pair must be generated
 - All your contacts must be notified and supplied with the new public key
- **Data encrypted using a public key can only be decrypted with the corresponding private key**
- **PGP is based on “public/private” key cryptography**

Getting Started with PGP

How are public/private key pairs generated?

- Oversimplifying a bit again, but they are essentially based on mathematical operations involving two really, really large prime numbers
- Prime numbers have been proven to have no known predictive pattern
- Finding prime numbers is fast and easy for small numbers
 - 14, 24, 49, etc
 - Even?...divisible by 2
 - Last digit is 5 or 0?...divisible by 5
 - And so on...
 - A LOT harder and slower as the numbers get bigger – making it practically impossible

Getting Started with PGP

What is this number?

$(2^{57885161}) - 1$

(To write it out in decimal form would require **17.425.170** digits - at 1 digit per second, it would take more than 200 days, non-stop)

Getting Started with PGP

The (Currently) Largest Known Prime Number

$(2^{57885161})-1$

Source: primes.utm.edu/largest.html
(A really good site for “Stupid Number Tricks”)

Getting Started with PGP

PGP Public/Private Key Pair Strength

- The public key is mathematically derived from the private key
- The private key relies on the “computational difficulty” of deriving the large primes used to generate it
- Private key lengths of 1024 bits are probably OK, but 2048 is the accepted standard for most users
- Key lengths over 2048 bits are more secure, but tend to eat up processing power

Getting Started with PGP

Recommended key size

Table 4: Recommended algorithms and minimum key sizes

Algorithm security lifetimes	Symmetric key algorithms (Encryption & MAC)	FFC (e.g., DSA, D-H)	IFC (e.g., RSA)	ECC (e.g., ECDSA)
Through 2010 (min. of 80 bits of strength)	2TDEA ²³ 3TDEA AES-128 AES-192 AES-256	Min.: $L = 1024$; $N = 160$	Min.: $k=1024$	Min.: $f=160$
Through 2030 (min. of 112 bits of strength)	3TDEA AES-128 AES-192 AES-256	Min.: $L = 2048$ $N = 224$	Min.: $k=2048$	Min.: $f=224$
Beyond 2030 (min. of 128 bits of strength)	AES-128 AES-192 AES-256	Min.: $L = 3072$ $N = 256$	Min.: $k=3072$	Min.: $f=256$

Algorithms

- Used to induce “randomness” in encoded message
- Helps reduce “known text” vulnerability
- “Encrypting” algorithms are designed to be reversible (they have to be, don’t they?)
 - Some **well-known** ones: DSA, RSA
- “Hashing” algorithms are “one-way”, i.e. irreversible
 - Used to provide “signature”, or “shared secret” verification
 - Used for password storage on most operating systems
 - Well-known ones include SHA-1 or SHA-2 (used by PGP)

Getting Started with PGP

Example: SHA1

Input	Output
-------	--------

1	356a192b7913b04c54574d18c28d46e6395428ab
2	da4b9237bacccdf19c0760cab7aec4a8359010b0
3	77de68daecd823babbb58edb1c8e14d7106e83bb
4	1b6453892473a467d07372d45eb05abc2031647a
5	ac3478d69a3c81fa62e60f5c3696165a4e5e6ac4

Getting Started with PGP

Well-known Algorithms

- The best-known algorithms are used to remove patterns and predictability from encoded messages
- **They are not secret** - in fact, they are made public and subjected to rigorous testing
- Encryption algorithms are reversible - they have to be

Getting Started with PGP

Where's the Security?

**In a public/private key cryptography environment, the strength lies in the length and protection of the private key -
and the algorithm**

Getting Started with PGP

Digital Signatures

- **Usually applied to e-mail messages to verify the sender's identity**
- **Sender "signs" the message with his private key**
 - Hashing algorithm is applied as well
 - Hashing also provides check on message integrity
- **Anyone who has sender's public key can apply it to verify sender's identity**
 - ONLY someone who has the corresponding private key could have sent it
 - Hashing also verifies that the message was not altered in transit

Getting Started with PGP

What does a “Public Key” look like?

-----END PGP PUBLIC KEY BLOCK-----

Hashed “fingerprint”:

1bf440b445d85c2ba39fb1365961ca7fafd5796e

(Hexadecimal)

Getting Started with PGP

How do I know that's really your public key?

- Generating public/private key pairs does NOT require any authentication - you can associate any name and e-mail address with a key pair you choose
- To be completely certain that a given public key actually belongs to the person it claims, you need to physically verify the person's identity and key in person
- Check the key fingerprint
- *Do not trust third parties (security by the weakest link)*

Getting Started with PGP

Public Key Distribution

- ~~Published on a (personal) website~~
- Via a CD/DVD or USB drive
- ~~Send as e-mail attachment~~
- Send as e-mail attachment via internal mailserver ehmm.
- ~~Upload it to a "key server"~~
- Use a QR code on the back of your business card with your key fingerprint
- Print it out on a sheet of paper, along with the fingerprint not very practical...
